In this Photoshop tutorial, you'll learn how to work with Photoshop's layer groups. Step 1: How to Create a New Photoshop Project To work with Photoshop's layer groups, you'll first have to create a new Photoshop document and name it appropriately. Click File in the menu bar on the top of the Photoshop window, then select New in the menu bar. Click Image, in the menu bar, then select Photoshop Document from the drop-down box, and click OK. Step 2: How to Create a New Layer Open the New Layer dialog box by clicking Layers in the menu bar. (If you aren't sure how, look at tutorial #10.) Drag the Down Arrow button to the left side of the dialog box. A palette for new layers appears. To create a new layer, click the Layer palette and then click OK to create a layer. If you select an image in the Editor window, the following dialog box appears. Step 3: Apply the Quick Selection Tool In the Layers window, click the Quick Selection tool in the Tools palette at the top of the screen and the Layers dialog box appears. The Layers palette and the Layers dialog box are the same. Select your image or drag it into the Layers dialog box. At the top right corner, the yellow arrow on the Layer Selection tool bar indicates that the image is selected in the Layers palette. Use the arrow keys to navigate with the Quick Selection tool and the Layers palette, and then use the Tab key to move through the different layers of your image. To select an entire layer or add it to the selection, click with the cursor in the Layer Selection dialog box. At the top of the dialog box, the mouse cursor indicates the layer. To add the selected layer to the selection, click the checkbox to the right of the layer. If there are multiple layers in your image, be aware that Photoshop does not indicate which layers belong to the selection by default. In order to view all the layers in the selection, drag the layer in the thumbnail area. This example uses the Quick Selection tool. Step 4: Determine the Best Layer to Convert to a Smart Object Open the Layer Selection dialog box and select the layer that you would like to convert to a Smart Object. Click the Convert to Smart Object button to the left of the layer.

### What's New in the?

The present invention relates to a process for producing an electronic component, such as a semiconductor device, that uses a resin material, and particularly relates to a process for producing a semiconductor device that uses a material of a specific organic compound. Along with a remarkable development of the information and telecommunication technologies, semiconductor devices have been remarkably miniaturized, while the degree of integration has been further increased. The rapid progress of the semiconductor technology has been made largely in accordance with the achievement of the cost reduction of the semiconductor devices. Furthermore, in terms of the reliability and the mass-productivity, the miniaturization and the multi-layer structure of the semiconductor devices have been carried out. In the recent years, as a counter measure to the miniaturization of the semiconductor devices, attention has been directed to a method of increasing the length of the wiring in the horizontal direction of the devices. When the wiring is formed in the horizontal direction, the wiring is capable of maintaining the reliability of the device and the durability of the inter-wire insulation film. Therefore, although the miniaturization of the semiconductor device can be achieved, it is still impossible to omit the miniaturization of the gate electrode of the transistor. That is to say, the use of the materials having higher electric resistance and higher heat resistance than those currently employed is indispensable. In the semiconductor device, the signal transmission speed of the semiconductor device has been increased in order to respond to the miniaturization and the multi-layer structure. For example, the aluminum (Al)-having excellent electric conductivity has been employed for the gate electrode of the transistor. However, the further miniaturization of the gate electrode has the disadvantage of disabling the suitable response to the further increase in the signal transmission speed of the semiconductor device. For this reason, attention has been directed to a method of using copper (Cu)-having excellent electric conductivity and higher resistance to electro-migration than that of Al, as the gate electrode. In the recent years, the study for the use of the materials of the group 14 in the periodic table, which contain nitrogen as a constituent element, for the use as the materials for the high-resistivity gate electrode has been made. For example, it is reported in the Japanese Unexamined Patent Publication No. 2-152622, the Japanese Unexamined Patent Publication No. 3-263924, and the Japanese Unexamined Patent Publication No. 3-18
